Let  $\gamma$  be a real constant with  $\gamma^2 \neq 1$  for the parametric functional

$$S\left[x,y\right] = \int_{0}^{1} \mathrm{d}t \, \left[ \sqrt{\dot{x}^{2} + 2\gamma \dot{x}\dot{y} + \dot{y}^{2}} - \lambda \left(x\dot{y} - \dot{x}y\right) \right], \quad \lambda > 0,$$

with the boundary conditions x(0) = y(0) = 0, x(1) = R > 0 and y(1) = 0.

(a) In order to show that the stationary paths of this parametric functional are given by the solutions of the equations

$$\frac{\mathrm{d}x}{\mathrm{d}s} + \gamma \frac{\mathrm{d}y}{\mathrm{d}s} = 2(c - \lambda y)$$
, and

$$\gamma \frac{\mathrm{d}x}{\mathrm{d}s} + \frac{\mathrm{d}y}{\mathrm{d}s} = 2\left(d + \lambda x\right),\,$$

where c and d are constants and

$$s(t) = \int_0^t dt \sqrt{\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2}$$
 (1.1)

Due: 1 April 2020

consider the following.

From the parametric functional,

$$\Phi = (\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{\frac{1}{2}} - \lambda (x\dot{y} - \dot{x}y), \quad \lambda > 0,$$

$$\frac{\partial \Phi}{\partial \dot{x}} = \frac{1}{2} (\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}} (2\dot{x} + 2\gamma \dot{y}) + \lambda y.$$

$$\frac{\partial \Phi}{\partial x} = -\lambda \dot{y}.$$

The Euler-Lagrange equation is given by

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{\partial \Phi}{\partial \dot{x}} \right) - \frac{\partial \Phi}{\partial x} = 0.$$

Substituting into the Euler-Lagrange equation for the derivatives obtained above gives,

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{1}{2} (\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}} \left( 2\dot{x} + 2\gamma \dot{y} \right) + \lambda y \right) + \lambda \dot{y} = 0,$$

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \left( \dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2 \right)^{-\frac{1}{2}} \left( \dot{x} + \gamma \dot{y} \right) + \lambda y \right) + \lambda \dot{y} = 0,$$

and integrating the above express with respect to t gives,

$$\left[ \left( \dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2 \right)^{-\frac{1}{2}} \left( \dot{x} + \gamma \dot{y} \right) + \lambda y \right] + \lambda y = 2c,$$

where c is an arbitrary constant.

$$(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}}(\dot{x} + \gamma \dot{y}) + 2\lambda y = 2c,$$

So,

$$(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}}(\dot{x} + \gamma \dot{y}) = 2(c - \lambda y). \tag{1.2}$$

Due: 1 April 2020

Now, from (1.1) the definition of s,

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \left(\dot{x}^2 + 2\gamma\dot{x}\dot{y} + \dot{y}^2\right)^{\frac{1}{2}},$$

and

$$\frac{\mathrm{d}t}{\mathrm{d}s} = \left(1/\frac{\mathrm{d}s}{\mathrm{d}t}\right) = \left(\dot{x}^2 + 2\gamma\dot{x}\dot{y} + \dot{y}^2\right)^{-\frac{1}{2}}.$$
 (1.3)

Substituting (1.3) into (1.2) gives,

$$\frac{\mathrm{d}t}{\mathrm{d}s}(\dot{x} + \gamma \dot{y}) = 2(c - \lambda y),$$

and noting that

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \dot{x}$$
 and  $\frac{\mathrm{d}y}{\mathrm{d}t} = \dot{y}$ ,

then

$$\frac{\mathrm{d}t}{\mathrm{d}s} \left( \frac{\mathrm{d}x}{\mathrm{d}t} + \gamma \frac{\mathrm{d}y}{\mathrm{d}t} \right) = 2 \left( c - \lambda y \right)$$

$$\frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}x}{\mathrm{d}t} + \gamma \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}t} = 2 \left( c - \lambda y \right),$$

thus, by the chain rule,

$$\frac{\mathrm{d}x}{\mathrm{d}s} + \gamma \frac{\mathrm{d}y}{\mathrm{d}s} = 2(c - \lambda y). \tag{1.4}$$

Similarly for  $\dot{y}$ 

$$\Phi = (\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{\frac{1}{2}} - \lambda (x\dot{y} - \dot{x}y), \quad \lambda > 0,$$

$$\frac{\partial \Phi}{\partial \dot{y}} = \frac{1}{2} (\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}} (2\gamma \dot{x} + 2\dot{y}) - \lambda x.$$

$$\frac{\partial \Phi}{\partial y} = \lambda \dot{x}.$$

The Euler-Lagrange equation is given by

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{\partial \Phi}{\partial \dot{y}} \right) - \frac{\partial \Phi}{\partial y} = 0.$$

Substituting into the Euler-Lagrange equation for the derivatives obtained above gives,

$$\frac{\mathrm{d}}{\mathrm{d}t} \left[ \frac{1}{2} \left( \dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2 \right)^{-\frac{1}{2}} \left( 2\gamma \dot{x} + 2\dot{y} \right) - \lambda x \right] - \lambda \dot{x} = 0,$$

$$\frac{\mathrm{d}}{\mathrm{d}t} \left[ \left( \dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2 \right)^{-\frac{1}{2}} \left( \gamma \dot{x} + \dot{y} \right) - \lambda x \right] - \lambda \dot{x} = 0,$$

and integrating the above express with respect to t gives,

$$(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}}(\gamma \dot{x} + \dot{y}) - \lambda x - \lambda x = 2d,$$

where d is an arbitrary constant. So,

$$(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}} (\gamma \dot{x} + \dot{y}) - 2\lambda x = 2d,$$

and thus,

$$(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2)^{-\frac{1}{2}} (\gamma \dot{x} + \dot{y}) = 2(d + \lambda x).$$

Recall, (1.3) from above,

$$\frac{\mathrm{d}t}{\mathrm{d}s} = \left(\dot{x}^2 + 2\gamma\dot{x}\dot{y} + \dot{y}^2\right)^{-\frac{1}{2}},$$

and hence,

$$\frac{\mathrm{d}t}{\mathrm{d}s} (\gamma \dot{x} + \dot{y}) = 2 (d + \lambda x),$$

$$\frac{\mathrm{d}t}{\mathrm{d}s} \left( \gamma \frac{\mathrm{d}x}{\mathrm{d}t} + \frac{\mathrm{d}y}{\mathrm{d}t} \right) = 2 (d + \lambda x),$$

$$\gamma \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}x}{\mathrm{d}t} + \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}t} = 2 (d + \lambda x),$$

Thus, by the chain rule,

$$\gamma \frac{\mathrm{d}x}{\mathrm{d}s} + \frac{\mathrm{d}y}{\mathrm{d}s} = 2(d + \lambda x).$$
(1.5)

Hence, the stationary paths of the given parametric functional are given by the solutions to equations (1.4) and (1.5).

#### (b) It can be shown that

$$\left(\frac{\mathrm{d}x}{\mathrm{d}s}\right)^2 + 2\gamma \frac{\mathrm{d}x}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}s} + \left(\frac{\mathrm{d}y}{\mathrm{d}s}\right)^2 = 1,$$

as follows.

From part (a)

$$\frac{\mathrm{d}s}{\mathrm{d}t} = \left(\dot{x}^2 + 2\gamma\dot{x}\dot{y} + \dot{y}^2\right)^{\frac{1}{2}},$$

and squaring both sides of the above expression gives,

$$\frac{\mathrm{d}s}{\mathrm{d}t} \cdot \frac{\mathrm{d}s}{\mathrm{d}t} = \left(\dot{x}^2 + 2\gamma \dot{x}\dot{y} + \dot{y}^2\right),\tag{1.6}$$

Again, recall that

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \dot{x}$$
 and  $\frac{\mathrm{d}y}{\mathrm{d}t} = \dot{y}$ ,

so that (1.6) becomes

$$\frac{\mathrm{d}s}{\mathrm{d}t} \cdot \frac{\mathrm{d}s}{\mathrm{d}t} = \left(\frac{\mathrm{d}x}{\mathrm{d}t} \cdot \frac{\mathrm{d}x}{\mathrm{d}t} + 2\gamma \frac{\mathrm{d}x}{\mathrm{d}t} \cdot \frac{\mathrm{d}y}{\mathrm{d}t} + \frac{\mathrm{d}y}{\mathrm{d}t} \cdot \frac{\mathrm{d}y}{\mathrm{d}t}\right),\tag{1.7}$$

Due: 1 April 2020

multiplying both sides of equation (1.7) by

$$\frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}t}{\mathrm{d}s}$$

gives,

$$\frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}s}{\mathrm{d}t} \cdot \frac{\mathrm{d}s}{\mathrm{d}t} = \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}x}{\mathrm{d}t} \cdot \frac{\mathrm{d}x}{\mathrm{d}t} + 2\gamma \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}x}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}t} + \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}t}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}t} \cdot \frac{\mathrm{d}y}{\mathrm{d}t}, \quad (1.8)$$

then by the chain rule (1.8) becomes

$$1 = \left(\frac{\mathrm{d}x}{\mathrm{d}s}\right)^2 + 2\gamma \frac{\mathrm{d}x}{\mathrm{d}s} \cdot \frac{\mathrm{d}y}{\mathrm{d}s} + \left(\frac{\mathrm{d}y}{\mathrm{d}s}\right)^2,\tag{1.9}$$

as required.

## (c) From equation (1.4)

$$\frac{\mathrm{d}x}{\mathrm{d}s} = 2\left(c - \lambda y\right) - \gamma \frac{\mathrm{d}y}{\mathrm{d}s}$$

and from equation (1.5)

$$\frac{\mathrm{d}y}{\mathrm{d}s} = 2\left(d + \lambda y\right) - \gamma \frac{\mathrm{d}x}{\mathrm{d}s}$$

Substituting into equation (1.4) for dy/ds gives,

$$\frac{\mathrm{d}x}{\mathrm{d}s} + \gamma \left( 2 \left( d + \lambda x \right) - \gamma \frac{\mathrm{d}x}{\mathrm{d}s} \right) = 2 \left( c - \lambda y \right),$$

$$\frac{\mathrm{d}x}{\mathrm{d}s} + 2\gamma \left( d + \lambda x \right) - \gamma^2 \frac{\mathrm{d}x}{\mathrm{d}s} = 2 \left( c - \lambda y \right),$$

$$\frac{\mathrm{d}x}{\mathrm{d}s} \left( 1 - \gamma^2 \right) + 2\gamma \left( d + \lambda x \right) = 2 \left( c - \lambda y \right),$$

$$\frac{\mathrm{d}x}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = 2 \left( c - \lambda y \right) - 2\gamma \left( d + \lambda x \right),$$

$$\frac{\mathrm{d}x}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = 2c - 2\lambda y - 2\gamma d - 2\gamma \lambda x,$$

$$\frac{\mathrm{d}x}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = -2\lambda \left( y + \gamma x \right) + 2 \left( c - \gamma d \right),$$

$$x' \left( 1 - \gamma^2 \right) = -X + D = D - X.$$

Therefore,

$$\left| (1 - \gamma^2)x' = D - X, \right|$$

(1.10) Where,  $D = 2 (c - \gamma d),$   $X = 2\lambda(x - y) \text{ and}$   $x' = \frac{dy}{ds}.$ 

Due: 1 April 2020

 $as\ required.$ 

Equation (1.5) is

$$\gamma \frac{\mathrm{d}x}{\mathrm{d}s} + \frac{\mathrm{d}y}{\mathrm{d}s} = 2 (d + \lambda x).$$

Substituting into equation (1.5) for dx/ds from equation (1.4) gives,

$$\gamma \left( 2(c - \lambda y) - \gamma \frac{\mathrm{d}y}{\mathrm{d}s} \right) + \frac{\mathrm{d}y}{\mathrm{d}s} = 2(d + \lambda x),$$

$$2\gamma (c - \lambda y) - \gamma^2 \frac{\mathrm{d}y}{\mathrm{d}s} + \frac{\mathrm{d}y}{\mathrm{d}s} = 2(d + \lambda x),$$

$$\frac{\mathrm{d}y}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = 2(d + \lambda x) - 2\gamma (c - \lambda y),$$

$$\frac{\mathrm{d}y}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = 2d + 2\lambda x - 2\gamma c + 2\gamma \lambda y,$$

$$\frac{\mathrm{d}y}{\mathrm{d}s} \left( 1 - \gamma^2 \right) = 2(d - \gamma c) + 2\lambda (x + \gamma y).$$

$$\therefore \qquad \boxed{\left(1-\gamma^2\right)y'=C+Y}.$$

(1.11) Where,  $C = 2 (d - \gamma c),$   $Y = 2\lambda (x + \gamma y) \text{ and}$   $y' = \frac{dy}{ds}$ 

as required.

Substituting for x' and y' from equations (1.10) and (1.11), respectively,  $y = \frac{1}{ds}$  into equation (1.9)

$$\frac{(D-X)^2}{(1-\gamma^2)^2} + 2\gamma \frac{(D-X)}{(1-\gamma^2)} \frac{(C+Y)}{(1-\gamma^2)} + \frac{(C+Y)^2}{(1-\gamma^2)^2} = 1$$

Expanding the above and cross multiplying by  $(1 - \gamma^2)^2$  gives,

$$D^{2} - 2DX + X^{2} + 2\gamma (D - X) (C + Y) + C^{2} + 2CY + Y^{2} = (1 - \gamma^{2})^{2},$$

$$D^{2} - 2DX + X^{2} + (2\gamma D - 2\gamma X) (C + Y) + C^{2} + 2CY + Y^{2} = (1 - \gamma^{2})^{2},$$

$$D^{2} - 2DX + X^{2} + 2\gamma CD + 2\gamma DY - 2\gamma CX - 2\gamma XY + C^{2} + 2CY + Y^{2} = (1 - \gamma^{2})^{2},$$

$$X^{2} + Y^{2} - 2\gamma XY + C^{2} + D^{2} + 2\gamma CD - 2DX + 2\gamma DY - 2\gamma CX + 2CY = (1 - \gamma^{2})^{2},$$

Collecting terms in just X and just Y gives,

$$X^{2}+Y^{2}-2\gamma XY+C^{2}+D^{2}+2\gamma CD-2X\left(D+\gamma C\right)+2Y\left(C+\gamma D\right)=\left(1-\gamma^{2}\right)^{2}. \tag{1.12}$$

Now, from above (see margin notes)

$$(D + \gamma C) = 2(c - \gamma d) + \gamma (2(d - \gamma c)),$$
  
=  $2c - 2\gamma d + 2\gamma d - 2\gamma^2 c,$   
=  $2c(1 - \gamma^2).$ 

Due: 1 April 2020

$$\begin{split} (C+\gamma D) =& 2\left(d-\gamma c\right) + \gamma \left(2\left(c-\gamma d\right)\right), \\ =& 2d-2\gamma c + 2\gamma c - 2\gamma^2 d, \\ =& 2d\left(1-\gamma^2\right). \end{split}$$

So,

$$D + \gamma C = 2c (1 - \gamma^2)$$
 and  $C + \gamma D = 2d (1 - \gamma^2)$ .

Substituting these expressions into equation (1.12) gives,

$$X^{2}+Y^{2}-2\gamma XY+C^{2}+D^{2}+2\gamma CD-4c\left(1-\gamma^{2}\right)X+4d\left(1-\gamma^{2}\right)Y=\left(1-\gamma^{2}\right)^{2}$$
, as required.

The boundary conditions are

$$x(0) = y(0) = 0$$
,  $x(1) = R > 0$ ,  $y(1) = 0$ .

Now, applying these boundary conditions to equation (1.12) and from the margin notes above we have:

$$X(t) = 2\lambda \left(\gamma x(t) + y(t)\right).$$

$$Y(t) = 2\lambda (x(t) + \gamma y(t)).$$

At t=0,

$$X(0) = 2\lambda (\gamma x(0) + y(0)) = 0.$$

$$Y(0) = 2\lambda (x(0) + \gamma y(0)) = 0.$$

Thus, equation (1.12) at t=0 reduces to

$$C^2 + D^2 + 2\gamma CD = (1 - \gamma^2)^2$$
.

At t=1,

$$X(1) = 2\lambda \left(\gamma x(1) + y(1)\right) = 2\lambda \gamma R.$$
  
$$Y(1) = 2\lambda \left(x(1) + \gamma y(1)\right) = 2\lambda R.$$

Thus, when applied to equation (1.12),

$$4\lambda^{2}\gamma^{2}R^{2} + 4\lambda^{2}R^{2} - 2\gamma (2\lambda\gamma R) (2\lambda R) - 4c (1 - \gamma^{2}) (2\lambda\gamma R) +4d (1 - \gamma^{2}) (2\lambda R) + C^{2} + D^{2} + 2\gamma CD = (1 - \gamma^{2})^{2}.$$

$$4\lambda^{2}\gamma^{2}R^{2} + 4\lambda^{2}R^{2} - 8\lambda^{2}\gamma^{2}R^{2} - 8c(1 - \gamma^{2})\lambda\gamma R + 8d(1 - \gamma^{2})\lambda R + C^{2} + D^{2} + 2\gamma CD = (1 - \gamma^{2})^{2}.$$

Note from above that  $C^2 + D^2 + 2\gamma CD = (1 - \gamma^2)^2$ , thus

$$4\lambda^{2}\gamma^{2}R^{2} + 4\lambda^{2}R^{2} - 8\lambda^{2}\gamma^{2}R^{2} - 8c(1 - \gamma^{2})\lambda\gamma R + 8d(1 - \gamma^{2})\lambda R = 0,$$

which, after dividing through by  $4\lambda R$ , gives

$$\lambda \gamma^2 R + \lambda R - 2\lambda \gamma^2 R - 2c \left(1 - \gamma^2\right) \gamma + 2d \left(1 - \gamma^2\right) = 0, \qquad \lambda, R \neq 0 \text{ and } \gamma^2 \neq 1$$
$$\lambda R - \lambda \gamma^2 R - 2c \left(1 - \gamma^2\right) \gamma + 2d \left(1 - \gamma^2\right) = 0,$$
$$\lambda R \left(1 - \gamma^2\right) - 2c \left(1 - \gamma^2\right) \gamma + 2d \left(1 - \gamma^2\right) = 0,$$

and dividing through by  $(1 - \gamma^2)$ , gives

$$\lambda R - 2c\gamma + 2d = 0.$$

Simplifying,

$$\lambda R - 2\left(c\gamma + d\right) = 0,$$

and noting that the quantity  $2(c\gamma + d)$  is equal to C, then

$$\lambda R + C = 0.$$

Finally,

$$C = -\lambda R, \quad R > 0, \tag{1.13}$$

as required.

Recall that  $C^2 + D^2 + 2\gamma CD = (1 - \gamma^2)^2$  and  $C = -\lambda R$ , R > 0.

Thus,

$$\lambda^{2}R^{2} + D^{2} + 2\gamma (-\lambda R) D = (1 - \gamma^{2})^{2},$$
  
$$D^{2} - 2\lambda \gamma RD + \lambda^{2}R^{2} - (1 - \gamma^{2})^{2} = 0.$$

Solving for D in the above quadratic,

$$D = \frac{2\lambda\gamma R \pm \sqrt{4\lambda^2 \gamma^2 R^2 - 4\left(\lambda^2 R^2 - (1 - \gamma^2)^2\right)}}{2},$$

$$D = \lambda\gamma R \pm \sqrt{\lambda^2 \gamma^2 R^2 - \lambda^2 R^2 + (1 - \gamma^2)^2},$$

$$D = \lambda\gamma R \pm \sqrt{\lambda^2 R^2 (\gamma^2 - 1) + (1 - \gamma^2)^2},$$

$$D = \lambda\gamma R \pm \sqrt{-\lambda^2 R^2 (1 - \gamma^2) + (1 - \gamma^2)^2}$$

It is seen that D will always have two real roots if  $\gamma^2 > 1$ , as in the expression below

$$D = \lambda \gamma R \pm \sqrt{-\lambda^2 R^2 (1 - \gamma^2) + (1 - \gamma^2)^2}$$

 $(1-\gamma^2)^2>0$  and  $(1-\gamma^2)<0$  and consequently  $-\lambda^2R^2(1-\gamma^2)>0$  making the entire quantity inside the radical positive.

Also, if  $\gamma^2 < 1$  the  $(1 - \gamma^2) > 0$  with  $-\lambda^2 R^2 (1 - \gamma^2) < 0$  and the quantity  $(1 - \gamma^2)^2 - \lambda^2 R^2 (1 - \gamma^2) > 0$  provided that  $\lambda^2 R^2 (1 - \gamma^2) < (1 - \gamma^2)^2$ , that is if  $\lambda R < \sqrt{(1 - \gamma^2)}$ , there will be two real roots of D.

Due: 1 April 2020

Conversely, if  $(1-\gamma^2)^2 - \lambda^2 R^2 (1-\gamma^2) < 0$  then  $\lambda^2 R^2 (1-\gamma^2) > (1-\gamma^2)^2$ , that is  $\lambda R > \sqrt{(1-\gamma^2)}$ , there will not be any real solutions of D.

# In order to show that the stationary path of the functional

$$S[y] = \int_0^v dx \, (y'^2 + y^2), y(0) = 1, y(v) = v, v > 0,$$

Due: 1 April 2020

is given by

Q 2.

$$y = \cosh x + B \sinh x, \quad 0 \le x \le v,$$

where B and v are given by the solutions of the equations

$$v = \cosh v + B \sinh v$$
 and  $B^2 - 1 = 2 \sinh v + 2B \cosh v$ ,

consider the following:

### (a) The integrand is

$$F = y'^2 + y^2,$$

and the Euler-Lagrange equation is given by

$$\frac{\mathrm{d}}{\mathrm{d}x} \left( \frac{\partial F}{\partial y'} \right) - \frac{\partial F}{\partial y} = 0,$$

where

$$\frac{\partial F}{\partial y'} = 2y', \quad \frac{\mathrm{d}}{\mathrm{d}x} \left( \frac{\partial F}{\partial y'} \right) = \frac{\mathrm{d}}{\mathrm{d}x} \left( 2y' \right) = 2y'' \quad \text{and} \quad \frac{\partial F}{\partial y} = 2y.$$

Thus, the Euler-Lagrange equation can be written as

$$2y'' - 2y = 0$$
 or  $\frac{d^2y}{dx^2} - y = 0$ .

The auxiliary equation is  $\lambda^2 - 1 = 0$  and has general solution

$$y = A\cosh(x) + B\sinh(x).$$

When x = 0, y(0) = 1, so

$$1 = A \cosh(0) + B \sinh(0)$$
, therefore  $A = 1$ .

When x = v, y(v) = v, so

$$v = \cosh(v) + B \sinh(v)$$
, therefore  $B = \frac{v - \cosh(v)}{\sinh(v)}$ .

Now, using the **Transversality Condition** in which the end of the curve can be expressed in the form y = g(x) and also noting that y(v) = v, then:

$$F + (q'(x) - y'(x)) F_{y'} = 0$$
 at  $x = v$ ,

Now, g(x) = x so g'(x) = 1 and from above  $F = y'^2 + y^2$ , hence

$$(y'^2 + y^2) + (1 - y') 2y' = 0,$$

$$y'^{2} + y^{2} + 2y' - 2y'^{2} = 0,$$
  
$$-y'^{2} + 2y' + y^{2} = 0 \text{ at } x = v.$$
 (2.1)

From above  $y(x) = \cosh x + B \sinh x$  and therefore  $y'(x) = \sinh x + B \cosh x$ 

Substituting these expressions into (2.1) at x = v gives,

$$-(\sinh v + B\cosh v)^{2} + 2(\sinh v + B\cosh v) + (\cosh v + B\sinh v)^{2} = 0$$

which simplifies to

$$-\sinh^{2} v - B^{2} \cosh^{2} v + 2 \sinh v + 2B \cosh v + \cosh^{2} v + B^{2} \sinh^{2} v = 0$$

Note:  $\cosh^2 v - \sinh^2 v = 1$ , so

$$1 - B^2 + 2\sinh v + 2B\cosh v = 0,$$

therefore, 
$$B^2 - 1 = 2 \sinh v + 2B \cosh v$$

(b) Using the equations found in part (a) it can be shown that v is given by the real solution(s) of f(v) = 0, where

$$f(v) = v^2 - 2v(1 + \sinh v)\cosh v + 1 + 2\sinh v.$$

as follows:

Recall from part (a) that,

$$v = \cosh v + B \sinh v, \tag{2.2}$$

$$B^{2} - 1 = 2\sinh v + 2B\cosh v, \qquad (2.3)$$

From (2.2)

$$B = \frac{v - \cosh v}{\sinh v}.\tag{2.4}$$

Substituting (2.4) into (2.3) gives,

$$\left(\frac{v - \cosh v}{\sinh v}\right)^2 - 1 = 2\sinh v + 2\left(\frac{v - \cosh v}{\sinh v}\right)\cosh v,$$

$$\frac{v^2 - 2v\cosh v + \left(\cosh^2 v - 2\sinh^2 v\right)}{\sinh^2 v} = 2\sinh v + 2\left(\frac{v - \cosh v}{\sinh v}\right)\cosh v,$$

$$\frac{v^2 - 2v\cosh v + 1}{\sinh^2 v} = \frac{2\sinh^2 v + 2v\cosh v - 2\cosh^2 v}{\sinh v},$$

$$\frac{v^2 - 2v\cosh v + 1}{\sinh v} = -2\left(\cosh^2 v - \sinh^2 v\right) + 2v\cosh v,$$

$$\frac{v^2 - 2v\cosh v + 1}{\sinh v} = -2 + 2v\cosh v,$$

$$v^2 - 2v\cosh v + 1 = 2\sinh v\left(v\cosh v - 1\right),$$

$$v^2 = 2v\cosh v - 1 + 2\sinh v\left(v\cosh v - 1\right),$$

$$v^2 = 2v\sinh v\cosh v - 2\sinh v + 2v\cosh v - 1,$$

$$v^2 = 2v\cosh v \left(\sinh v + 1\right) - 2\sinh v - 1,$$

(2.5)

(c) To deduce that there is only one stationary path, which is equivalent to proving that f(v) = 0 has exactly one solution for v > 0, consider the following.

 $\therefore f(v) = v^2 - 2v (1 + \sinh v) \cosh v + 1 + 2 \sinh v = 0.$ 

First, it is necessary to show that f(v) = 0 has at least one solution in the interval  $0 < v < \infty$ . Now f is continuous on [0,1] with f(0) > 0 and f(1) < 0. Thus, by the **Intermediate Value Theorem**, it follows that f(v) = 0 for some value of v in the interval (0,1) and hence in  $(0,\infty)$ . Consequently, f(v) = 0 has at least one solution in the interval  $0 < v < \infty$ .

$$f(0) = 1.0$$
  
$$f(1) = -2.363$$
  
rounded to 3 figures

Next, it is necessary to show that f(v) = 0 has at most one solution in the interval  $0 < v < \infty$ . Assume that it has more that one solution in this interval and choose two solutions within this interval; say at v = a and v = b and suppose a < b. Then, since f is continuous on the interval [a,b] and so differentiable on this interval, with f(a) = 0 and f(b) = 0 and it follows from **Rolle's Theorem** that f'(d) = 0 for some d in (a,b). However, f'(v) < 0 for all v > 0 (see below). Hence this shows that f'(v) cannot be zero in the interval (a,b) and there exists a contradiction, thus showing that f(x) = 0 has at most one solution in the interval  $0 < v < \infty$ . This coupled with the fact that f(v) = 0 has at least one solution in the interval  $0 < v < \infty$  leads to the conclusion that this equation has exactly one solution in the given interval.

$$\begin{split} f(v) &= v^2 - 2v \left( 1 + \sinh v \right) \cosh v + 1 + 2 \sinh v, \\ f'(v) &= \frac{\mathrm{d}}{\mathrm{d}v} \left( v^2 \right) - 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( v \left( 1 + \sinh v \right) \cosh v \right) + \frac{\mathrm{d}}{\mathrm{d}v} \left( 1 \right) + 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( \sinh v \right), \\ &= 2v - 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( v \left( 1 + \sinh v \right) \cosh v \right) + 2 \cosh v, \\ &= 2v - 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( v \cosh v + v \sinh v \cosh v \right) + 2 \cosh v, \\ &= 2v - 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( v \cosh v \right) - 2 \frac{\mathrm{d}}{\mathrm{d}v} \left( v \sinh v \cosh v \right) + 2 \cosh v, \end{split}$$

$$=2v - 2(v \sinh v + \cosh v) - 2\frac{\mathrm{d}}{\mathrm{d}v}(v \sinh v \cosh v) + 2\cosh v,$$
  
$$=2v - 2v \sinh v - 2\cosh v - 2\frac{\mathrm{d}}{\mathrm{d}v}(v \sinh v \cosh v) + 2\cosh v,$$

#### Simplifying

$$f'(v) = 2v (1 - \sinh v) - 2 \frac{d}{dv} (v \sinh v \cosh v),$$

$$= 2v (1 - \sinh v) - 2 (\sinh v \cosh v + v \cosh v \cosh v + v \sinh v \sinh v),$$

$$= 2v (1 - \sinh v) - 2 \sinh v \cosh v - 2v (\cosh^2 v + \sinh^2 v),$$

$$= 2 (v (1 - \sinh v) - \sinh v \cosh v - v (\cosh^2 v + \sinh^2 v)),$$

$$= 2 (v - v \sinh v - \sinh v \cosh v - v \cosh^2 v - v \sinh^2 v)$$

Inspection of the last expressions shows that f'(v) is negative for all v > 0.

Q 3.

(a) Heron's formula for the area A of a triangle with sides of length a, b, c > 0 is given by

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$
, where  $s = \frac{a+b+c}{2}$ .

The method of Lagrange multipliers will be used to show that for a triangle with a fixed perimeter P = a + b + c = 2s, then its area is maximised when the triangle is an equilateral, as follows.

For this problem  $f(a, b, c) = \sqrt{s(s-a)(s-b)(s-c)}$ , and g(a, b, c) = a + b + c - 2s, so that the auxiliary function is

$$\overline{F}(a, b, c, \lambda) = f(a, b, c) - \lambda g(a, b, c), = \sqrt{s(s-a)(s-b)(s-c)} - \lambda (a+b+c-2s), \qquad s = \frac{a+b+c}{2}$$

with each of a, b and c > 0. The following three equations relating a, b, c and  $\lambda$  are required:

$$\frac{\partial \overline{F}}{\partial a} = 0$$
,  $\frac{\partial \overline{F}}{\partial b} = 0$  and  $\frac{\partial \overline{F}}{\partial c} = 0$ .

So,

$$\frac{\partial \overline{F}}{\partial a} = \frac{-s(s-b)(s-c)}{2\sqrt{s(s-a)(s-b)(s-c)}} - \lambda = 0,$$

$$\frac{\partial \overline{F}}{\partial b} = \frac{-s(s-a)(s-c)}{2\sqrt{s(s-a)(s-b)(s-c)}} - \lambda = 0,$$

$$\frac{\partial \overline{F}}{\partial c} = \frac{-s(s-a)(s-b)}{2\sqrt{s(s-a)(s-b)(s-c)}} - \lambda = 0.$$

So,

$$s(s-b)(s-c) = -2\lambda A,$$
  

$$s(s-a)(s-c) = -2\lambda A,$$
  

$$s(s-a)(s-b) = -2\lambda A \text{ and }$$
  

$$a+b+c-2s=0.$$

Thus,

$$s(s-b)(s-c) = s(s-a)(s-c) = s(s-a)(s-b)$$
 and  $s \neq 0, a, b, c$ .

Consequently, a = b = c.

(b) To find, in terms of the fixed perimeter P = 2s, the maximum area of a right-angled triangle with perimeter P consider the following.

This problem has two constraints. Therefore, there are two Lagrange multipliers,  $\lambda$  and  $\mu$ , one for each constraint. The auxiliary equation is

Due: 1 April 2020

$$\overline{F}(a,b,c,\lambda,\mu) = f(a,b,c) - \lambda g_1(a,b,c) - \mu g_2(a,b,c),$$

and finding the stationary points of this is achieved by finding the solutions of

$$\frac{\partial \overline{F}}{\partial a} = 0, \quad \frac{\partial \overline{F}}{\partial b} = 0, \quad \frac{\partial \overline{F}}{\partial c} = 0,$$

The first constraint relates to the triangle being right angled. Assuming side c is the hypotenuse, then Pythagoras' Theorem

$$a^2 + b^2 = c^2$$

and the constraint becomes  $g_1(a, b, c) = a^2 + b^2 - c^2$ .

The second constraint relates to the triangle having a fixed perimeter as in part (a), namely  $g_2(a, b, c) = a + b + c - 2s$ .

Thus, the auxiliary equation given above becomes

$$\overline{F} = \sqrt{s(s-a)(s-b)(s-c)} - \lambda (a^2 + b^2 - c^2) - \mu (a+b+c-2s).$$

$$\frac{\mathrm{d}F}{\mathrm{d}a} = \frac{-s(s-b)(s-c)}{2\sqrt{s(s-a)(s-b)(s-c)}} - 2\lambda a - \mu = 0,$$

$$\frac{\mathrm{d}\overline{F}}{\mathrm{d}b} = \frac{-s(s-a)(s-c)}{2\sqrt{s(s-a)(s-b)(s-c)}} - 2\lambda b - \mu = 0,$$

$$\frac{\mathrm{d}\overline{F}}{\mathrm{d}c} = \frac{-s(s-a)(s-b)}{2\sqrt{s(s-a)(s-b)(s-c)}} - 2\lambda c - \mu = 0.$$

Recall that  $A = \sqrt{s(s-a)(s-b)(s-c)}$ , so

$$\frac{-s(s-b)(s-c)}{2A} - 2\lambda a - \mu = 0,$$
(3.1)

$$\frac{-s(s-a)(s-c)}{2A} - 2\lambda b - \mu = 0, (3.2)$$

$$\frac{-s(s-a)(s-b)}{2A} + 2\lambda c - \mu = 0.$$
 (3.3)

Subtracting (3.2) from (3.1) gives,

$$\left(\frac{-s(s-b)(s-c)}{2A} - 2\lambda a - \mu\right) - \left(\frac{-s(s-a)(s-c)}{2A} - 2\lambda b - \mu\right) = 0$$

$$\frac{-s(s-b)(s-c)}{2A} - 2\lambda a - \mu + \frac{s(s-a)(s-c)}{2A} + 2\lambda b + \mu = 0$$

$$\frac{-s(s-b)(s-c)}{2A} - 2\lambda a + \frac{s(s-a)(s-c)}{2A} + 2\lambda b = 0$$

$$\frac{-s(s-b)(s-c)}{2A} + \frac{s(s-a)(s-c)}{2A} + 2\lambda(b-a) = 0$$

$$\frac{-s(s-b)(s-c) + s(s-a)(s-c)}{2A} + 2\lambda(b-a) = 0$$

$$s(s-c)\frac{-(s-b) + (s-a)}{2A} + 2\lambda(b-a) = 0$$

$$s(s-c)\frac{-s+b+s-a}{2A} + 2\lambda(b-a) = 0$$

$$\frac{s(s-c)(b-a)}{2A} + 2\lambda(b-a) = 0$$

$$(b-a)\left(\frac{s(s-c)}{2A} + 2\lambda\right) = 0$$

$$(b-a)(s(s-c) + 4A\lambda) = 0$$

and so b - a = 0 or  $s(s - c) + 4A\lambda = 0$  with  $s \neq 0, c$ .

Subtracting (3.3) from (3.1) gives,

∴  $-4A\lambda = s(s-c)$  and this result will be used below.

$$\frac{-s(s-b)(s-c)}{2A} + \frac{s(s-a)(s-b)}{2A} - 2\lambda(a+c) = 0,$$

$$\frac{-s(s-b)(s-c) + s(s-a)(s-b)}{2A} - 2\lambda(a+c) = 0,$$

$$s(s-b)\frac{-(s-c) + (s-a)}{2A} - 2\lambda(a+c) = 0,$$

$$s(s-b)\frac{-s+c+s-a}{2A} - 2\lambda(a+c) = 0,$$

$$\frac{s(s-b)(c-a)}{2A} - 2\lambda(a+c) = 0,$$

$$s(s-b)(c-a) - 2\lambda(a+c) = 0,$$

$$s(s-b)(c-a) - 4A\lambda(a+c) = 0,$$
recall that 
$$-4A\lambda = s(s-c), \text{ so}$$

$$s(s-b)(c-a) + s(s-c)(a+c) = 0,$$

$$sc - sa - bc + ab + sa + sc - ac - c^2 = 0,$$

$$2sc - bc + ab - ac - c^2 = 0,$$

$$ab + c(2s - a - b - c) = 0.$$

Now it is noted that 2s - a - b - c = 0, but ab = 0 is not possible so a = b,  $s = \frac{a + b + c}{2}$  and by Pythagoras' Theorem  $c = \sqrt{a^2 + a^2} = a\sqrt{2}$  and the perimeter  $P = a + b + c = a + a + a\sqrt{2} = a(2 + \sqrt{2})$ .

The area of a right-angled triangle is given by  $A = \frac{1}{2}ab = \frac{1}{2}a^2$ . From the foregoing  $a = \frac{P}{\left(2 + \sqrt{2}\right)}$ . So,

$$A = \frac{1}{2} \left( \frac{P}{2 + \sqrt{2}} \right)^2 = \frac{P^2}{12 + 8\sqrt{2}} = \frac{3 - 2\sqrt{2}}{4} P^2.$$

# Q 4. The method of Lagrange multipliers will be used to find the function y(x) that makes the functional

$$S[y] = \int_1^2 \mathrm{d}x \, x^2 y^2$$

Due: 1 April 2020

stationary subject to the two constraints

$$\int_{1}^{2} \mathrm{d}x \, xy = 1 \quad \text{and} \quad \int_{1}^{2} \mathrm{d}x \, x^{2}y = 2.$$

Given the functional

$$S[y] = \int_1^2 \mathrm{d}x \, x^2 y^2$$

and the constraints

$$\int_{1}^{2} dx \, xy = 1$$
 and  $\int_{1}^{2} dx \, x^{2}y = 2$ .

then

$$\overline{F} = x^2 y^2 - \lambda xy - \mu x^2 y,$$

where  $\lambda$  and  $\mu$  are Lagrange multipliers. As  $\overline{F}$  does not include the derivative of y then the Euler-Lagrange equation is simply given by

$$\frac{\mathrm{d}\overline{F}}{\mathrm{d}u} = 2x^2y - \lambda x - \mu x^2 = 0,$$

which, upon dividing through by x gives

$$2xy - \lambda - \mu x = 0.$$

Rearranging the above in terms of y gives the general solution,

$$y(x)\frac{\lambda + \mu x}{2x}$$

Both  $\lambda$  and  $\mu$  can be found by using the constraints as follows.

$$C_1[y] = \int_1^2 dx \frac{x(\lambda + \mu x)}{2x^{-1}} = 1,$$

which, after integration and the application of the limits of integration gives,

$$\frac{1}{2}\lambda + \frac{3}{4}\mu = 1.$$

$$C_2[y] = \int_1^2 dx \frac{x^{2}(\lambda + \mu x)}{2x^{2}} = 2,$$
(4.1)

which, again after integration and the application of the limits of integration gives,

$$\frac{3}{4}\lambda + \frac{7}{6}\mu = 2. {(4.2)}$$

Due: 1 April 2020

Solving for  $\lambda$  and  $\mu$  from equations (4.1) and (4.2) gives,

$$\lambda = -16$$
 and  $\mu = 12$ .

Hence,

$$y(x) = \frac{2(3x-4)}{r}.$$

The stationary value of S[y] is calculated as follows.

$$S[y] = \int_{1}^{2} dx \, x$$

$$= \int_{1}^{2} dx \, x^{2} \left(\frac{2(3x-4)}{x}\right)^{2},$$

$$= \int_{1}^{2} dx \, \frac{x^{2} \cdot 4(3x-4)^{2}}{x^{2}},$$

$$= \int_{1}^{2} dx \, 4(9x^{2}-24x+16),$$

$$= 4 \int_{1}^{2} dx \, (9x^{2}-24x+16),$$

$$= 4 \left[\frac{9}{3}x^{3} - \frac{24}{2}x^{2} + 16x\right]_{1}^{2},$$

$$= 4 \left[3x^{3} - 12x^{2} + 16x\right]_{1}^{2},$$

$$= 4 \left(3 \cdot 8 - 12 \cdot 4 + 16 \cdot 2\right) - 4 \left(3 - 12 + 16\right),$$

$$= 4 \left(24 - 48 + 32\right) - 4 \left(7\right),$$

$$= 4 \left(8\right) - 4 \left(7\right),$$

$$= 4.$$

$$S[y] = \int_0^a dx \, (y'^2 + 2by), \quad y(a) = 0,$$

with a natural boundary condition at x = 0 and subject to the constraint

$$C[y] = \int_0^a \mathrm{d}x \, y = c,$$

is given by

$$y(x) = \frac{3c}{2a^3} (a^2 - x^2),$$

as follows. The Euler-Lagrange equation is given by

$$\frac{\mathrm{d}}{\mathrm{d}x} \left( \frac{\partial F}{\partial y'} \right) - \frac{\partial F}{\partial y} = 0.$$

Now,

 $\overline{F} = y'^2 + 2by - \lambda y$ , where  $\lambda$  is a Lagrange multiplier.

$$\frac{\partial \overline{F}}{\partial y} = 2b - \lambda$$
 and  $\frac{\partial \overline{F}}{\partial y'} = 2y'$ .

The Euler-Lagrange equation becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(2y') - (2b - \lambda) = 0,$$
$$2y'' - 2b + \lambda = 0.$$

Hence,  $y'' = b - \frac{\lambda}{2}$ ,  $y' = \left(b - \frac{\lambda}{2}\right)x + c_1$  and  $y = \left(\frac{b}{2} - \frac{\lambda}{4}\right)x^2 + c_1x + c_2$ , where  $c_1$  and  $c_2$  are arbitrary constants. Applying the boundary condition y(a) = 0

$$y(a) = \left(\frac{b}{2} - \frac{\lambda}{4}\right)a^2 + c_1a + c_2 = 0.$$

Q 6.

(a) The model of tumour growth under radiotherapy from time t = 0 to  $t = t_1 > 0$  is given as

$$\frac{\mathrm{d}C}{\mathrm{d}t} = -C \, \log \left( \frac{C}{C_{max}} \right) - \frac{DC}{1+D},\tag{6.1}$$

Due: 1 April 2020

where, at time t, C(t) is the size of the tumour,  $C_{max} > 0$  is the maximum size of the tumour, a constant, so that  $0 < C(t) \le C_{max}$ , and  $D(t) \ge 0$  is the rate at which the drug is administered.

Now, making a change of variable

$$x = \log\left(\frac{C}{C_{max}}\right),\,$$

then (6.1) becomes

$$\begin{split} \frac{\mathrm{d}x}{\mathrm{d}t} &= \frac{\mathrm{d}C}{\mathrm{d}t} \cdot \frac{\mathrm{d}x}{\mathrm{d}C}, \\ \frac{\mathrm{d}x}{\mathrm{d}t} &= \frac{\mathrm{d}C}{\mathrm{d}t} \cdot \frac{1}{C}, \\ \frac{\mathrm{d}x}{\mathrm{d}t} &= \left[ \mathcal{C} \log \left( \frac{C}{C_{max}} \right) - \frac{D\mathcal{C}^{1}}{1+D} \right] \cdot \frac{1}{\mathcal{C}^{1}}, \\ \frac{\mathrm{d}x}{\mathrm{d}t} &= -\log \left( \frac{C}{C_{max}} \right) - \frac{D}{1+D}, \\ \text{thus,} \quad \frac{\mathrm{d}x}{\mathrm{d}t} &= -x - \frac{D}{1+D}, \quad \text{where } -\infty < x \leq 0. \end{split}$$

(b) We are told that:

It is required to reduce the size of the tumour from  $C_0$  at t = 0 to  $C_1$  at  $t = t_1$ . Let  $x_0 = \log(C_0/C_{max})$  and  $x_1 = \log(C_1/C_{max})$ . For the health of the patient, it is desired to minimise the total amount of drug administered, which is given by the functional

$$S[D] = \int_0^{t_1} \mathrm{d}t \ D(t).$$

So, by expressing D in terms of x and  $\dot{x} = dx/dt$  it should be possible to show that S[D] may be written as

$$S[x] = -\int_0^{t_1} dt \, \frac{\dot{x} + x}{1 + \dot{x} + x}.$$

From part (a)

$$\dot{x} = -x - \frac{D}{1+D},$$

$$\dot{x} + x = -\frac{D}{1+D},$$

$$(\dot{x} + x)(1+D) = -D,$$

$$(\dot{x} + x) + D(\dot{x} + x) = -D,$$

$$D(\dot{x} + x) + D = -(\dot{x} + x),$$

$$D(\dot{x} + x + 1) = -\dot{x} - x,$$

$$D = \frac{-\dot{x} - x}{\dot{x} + x + 1}.$$

So

$$S[x] = -\int_0^{t_1} \mathrm{d}t \; \frac{\dot{x} + x}{\dot{x} + x + 1} \qquad \text{as required.}$$

(c) To show that the Euler-Lagrange equation for S[x] is given by

$$2\ddot{x} + 3\dot{x} + x = -1$$
, where  $\ddot{x} = d^2x/dt^2$ ,

consider the following.

The Euler-Lagrange equation is given by

HB p17.

Due: 1 April 2020

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{\partial F}{\partial \dot{x}} \right) - \frac{\partial F}{\partial x} = 0, \qquad y(a) = A, \quad y(b) = B.$$

$$\text{Let, } F = \frac{\dot{x} + x}{\dot{x} + x + 1},$$

then using the quotient rule to determine  $\partial F/\partial \dot{x}$  and  $\partial F/\partial x$ 

$$\frac{\partial}{\partial \dot{x}} \left( \frac{u}{v} \right) = \left[ v \frac{\partial u}{\partial \dot{x}} - u \frac{\partial v}{\partial \dot{x}} \right] / v^2 \quad \text{where, } u = \dot{x} + x \text{ and } v = \dot{x} + x + 1.$$

$$\frac{\partial F}{\partial \dot{x}} = \frac{(\dot{x} + x + 1) \cdot 1 - (\dot{x} + x) \cdot 1}{(\dot{x} + x + 1)^2} = \frac{1}{(\dot{x} + x + 1)^2},$$
$$\frac{\partial F}{\partial x} = \frac{(\dot{x} + x + 1) \cdot 1 - (\dot{x} + x) \cdot 1}{(\dot{x} + x + 1)^2} = \frac{1}{(\dot{x} + x + 1)^2}.$$

$$\frac{\mathrm{d}}{\mathrm{d}t} \left( \frac{\partial F}{\partial \dot{x}} \right) = \frac{\mathrm{d}}{\mathrm{d}t} \left( \dot{x} + x + 1 \right)^{-2},$$

$$= -2 \left( \dot{x} + x + 1 \right)^{-3} \left( \ddot{x} + \dot{x} \right),$$

$$= \frac{-2 \left( \ddot{x} + \dot{x} \right)}{\left( \dot{x} + x + 1 \right)^{3}}.$$

Therefore, the Euler-Lagrange equation is

$$-\frac{2(\ddot{x}+\dot{x})}{(\dot{x}+x+1)^3} - \frac{1}{(\dot{x}+x+1)^2} = 0,$$

$$\frac{2(\ddot{x}+\dot{x})}{(\dot{x}+x+1)^3} = -\frac{1}{(\dot{x}+x+1)^2},$$

$$\frac{2(\ddot{x}+\dot{x})}{(\dot{x}+x+1)} = -1,$$

$$2(\ddot{x}+\dot{x}) = -(\dot{x}+x+1),$$

$$2(\ddot{x}+\dot{x}) + (\dot{x}+x) = -1,$$

$$2\ddot{x}+3\dot{x}+x=-1, \text{ as required.}$$

$$(6.2) \quad \ddot{x} = d^2x/dt^2.$$

(d) Now solving the second-order linear ordinary differential equation (6.2) with the boundary conditions  $x(0) = x_0$  and  $x(t_1) = x_1$  as follows.

The auxiliary equation is

$$2\lambda^2 + 3\lambda + 1 = 0.$$

This has roots  $\lambda_1 = -1$  and  $\lambda_2 = -\frac{1}{2}$ . These roots are real and different so the complementary function is given by

$$y_c = c_1 e^{-t} + c_2 e^{-\frac{1}{2}t}$$
, where  $c_1$  and  $c_2$  are arbitrary constants.

Using the method of undetermined coefficients to determine the particular solution to (6.2) as follows.

The particular solution to

$$2\frac{d^2x(t)}{dt^2} + 3\frac{dx(t)}{dt} + x(t) = -1,$$

is of the form

$$x_p(t) = a_1,$$

where  $a_1$  is an unknown constant to be determined as follows:

$$\frac{\mathrm{d}x(t)}{\mathrm{d}t} = \frac{\mathrm{d}}{\mathrm{d}t}(a_1) = 0,$$

and therefore

$$\frac{\mathrm{d}^2 x(t)}{\mathrm{d}t^2} = 0.$$

Substituting the particular solution  $x_p(t)$  in to (6.2) gives

$$2 \times 0 + 3 \times 0 + a_1 = -1.$$

Therefore,  $a_1 = -1$  and the general solution is

$$x(t) = c_1 e^{-t} + c_2 e^{-\frac{1}{2}t} - 1. (6.3)$$

Now using the boundary conditions to solve for the unknown constants  $c_1$  and  $c_2$  as follows.

At t = 0,  $x(0) = x_0$  and substituting this condition into (6.3) gives,

$$c_1 + c_2 - 1 = x_0. (6.4)$$

Due: 1 April 2020

At  $t = t_1$ ,  $x(t_1) = x_1$  and substituting this condition into (6.3) gives,

$$c_1 e^{-t_1} + c_2 e^{-\frac{1}{2}t_1} - 1 = x_1 \tag{6.5}$$

From (6.4)

$$c_1 = (x_0 + 1) - c_2 (6.6)$$

Substituting into (6.5) for  $c_1$  from (6.6) and rearranging in terms of  $c_2$ 

$$(x_0 + 1) e^{-t_1} - c_2 e^{-t_1} + c_2 e^{-\frac{1}{2}t_1} = x_1 + 1,$$

$$(x_0 + 1) e^{-t_1} + c_2 \left( e^{-\frac{1}{2}t_1} - e^{-t_1} \right) = (x_1 + 1),$$

$$c_2 \left( e^{-\frac{1}{2}t_1} - e^{-t_1} \right) = (x_1 + 1) - (x_0 + 1) e^{-t_1},$$

$$c_2 = \frac{(x_1 + 1) - (x_0 + 1) e^{-t_1}}{\left( e^{-\frac{1}{2}t_1} - e^{-t_1} \right)}.$$

$$(6.7)$$

Substituting for  $c_2$  in (6.6) from (6.7)

$$c_{1} = (x_{0} + 1) - \left[ \frac{(x_{1} + 1) - (x_{0} + 1) e^{-t_{1}}}{\left(e^{-\frac{1}{2}t_{1}} - e^{-t_{1}}\right)} \right],$$

$$c_{1} = \frac{(x_{0} + 1) \left(e^{-\frac{1}{2}t_{1}} - e^{-t_{1}}\right) - (x_{1} + 1) + (x_{0} + 1) e^{-t_{1}}}{\left(e^{-\frac{1}{2}t_{1}} - e^{-t_{1}}\right)}$$

$$c_{1} = \frac{(x_{0} + 1) e^{-\frac{1}{2}t_{1}} - (x_{0} + 1) e^{-t_{1}} - (x_{1} + 1) + (x_{0} + 1) e^{-t_{1}}}{\left(e^{-\frac{1}{2}t_{1}} - e^{-t_{1}}\right)}$$

$$c_{1} = \frac{(x_{0} + 1) e^{-\frac{1}{2}t_{1}} - (x_{1} + 1)}{\left(e^{-\frac{1}{2}t_{1}} - e^{-t_{1}}\right)} = \alpha.$$
(6.8)

Therefore, from (6.4)

$$c_2 = (x_0 + 1) - \alpha. (6.9)$$

Substituting into (6.3) for  $c_1$  and  $c_2$  from (6.8) and (6.9) respectively gives,

$$x(t) = \alpha e^{-t} + (x_0 + 1 - \alpha) e^{-\frac{1}{2}t} - 1$$
 (\alpha given in (6.8)),

as required.
